Terms and Conditions of Use

Except as permitted by the applicable copyright law, you may not reproduce or make this material available to any third party without the prior written permission from the copyright holder(s). Copyright law allows the following uses of this material without prior permission:

- you may download, save and print a copy of this material for your personal use only;
- you may share the EUR portal link to this material.

In case the material is published with an open access license (e.g. a Creative Commons (CC) license), other uses may be allowed. Please check the terms and conditions of the specific license.

Take-down policy

If you believe that this material infringes your copyright and/or any other intellectual property rights, you may request its removal by contacting us at the following email address: openaccess.library@eur.nl. Please provide us with all the relevant information, including the reasons why you believe any of your rights have been infringed. In case of a legitimate complaint, we will make the material inaccessible and/or remove it from the website.

Propositions

- I. With few exceptions, traditional candidate gene studies of complex behavioral traits did not yield any real insights into the genetics of behavioral phenotypes because of small sample sizes leading to low statistical power, and an inability to address methodological challenges such as population stratification and undisclosed multiple-hypothesis testing (Chapter 2).
- II. Even for behavioral phenotypes that are mostly environmentally determined, a well-powered GWAS can successfully identify replicable genetic associations (Chapters 3 and 4).
- III. Because educational attainment is measured in large numbers of individuals, it will continue to be useful as a proxy phenotype in efforts to characterize the genetic influences of related phenotypes, including cognition and neuropsychiatric disease (Chapter 4).
- IV. The number of credibly established genetic associations identified via genome-wide association studies, and the predictive power of polygenic scores derived from the findings of such studies, is rapidly increasing and will continue to increase in the years ahead (Chapters 3 and 4).
- V. Polygenic scores and quasi-experimental methods for causal inference will usher in an era of more credible research on gene-by-environment interactions (Chapter 5).
- VI. The tradeoff between sample size and cross-cohort heterogeneity is quantifiable and should therefore be accounted for in the design phase of studies (Chapter 6).
- VII. Bad quality control is detrimental to statistical power in genome-wide association studies.
- VIII. Science should not be conceived as a race to be the first on the finish line, but as a collaborative effort to advance the research frontier.

- IX. Any entity capable of intelligently designing something as improbable as a Dutchman's Pipe would have to be even more improbable than a Dutchman's Pipe. (*R. Dawkins*)

- X. If you trust in yourself... and believe in your dreams... and follow your star... you'll still get beaten by people who spent their time working hard and learning things and weren't so lazy. (*T. Pratchett*)

- XI. Somewhere, something incredible is waiting to be known. (*C. Sagan*)
